1

Gather public data

Sec. 3.1, 4

Well and host positions, equipment costs, failure rates, 10 years of wave data

2

Put a price on each failure

Sec. 3.4–3.7

Downtime = mobilization + waiting on weather + repair; cost = vessel hire + lost oil

3

Optimize the layout twice

Sec. 3.8

Case 1: cheapest to build. Case 2: highest NPV once failure costs are included

4

Check the answer

Sec. 3.9

Simulate random failures over the field life; add a risk-averse version of Case 2

5

Test the assumptions

Sec. 3.10

Change one input at a time; map where the best layout switches

Answer: does the optimal layout change when failures are costed, and by how much?
